Math 130 04 – A Survey of Calculus

Practice Exam

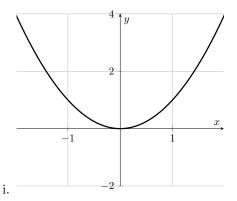

December 8, 2022 Time: 2 hours

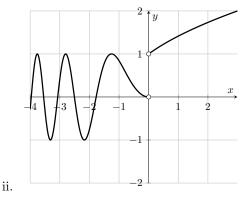

Instructions:

- You have exactly 2 hours to finish the exam.
- You are allowed to use your personal notes (paper only) and a graphing calculator. No other devices (computers, cell phones, tablets) may be used.
- You **must** write your name and student ID at the top of the first page, and you **must** initial every page that you use.
- This exam has five questions, each worth five points. Your goal is to get 18 points in total.
- Any extra points (> 18) will eventually count towards increasing your grade ($A \rightarrow A^+$, $B^+ \rightarrow A$, $B^- \rightarrow B$, and so on) at the end of the semester.
- Each question is divided into subquestions. The points that each subquestion is worth are indicated next to it.
- Write your answers clearly and neatly in the space provided after each question.
- Ask for extra sheets of paper if you need them.
- Number your answers correctly (especially if you're using extra sheets of paper).
- Justify your answers **fully and clearly.** Answers with no explanation (*even if the final calculation is correct*) are worth **zero** points. Answers with a full and correct explanation but a calculation error are worth more than 90% of the points.

Your Student ID:

1. (a) (2 points) Which of the following graphs represent real functions? Which of the functions is continuous over the interval [-1,1]?

Solution:

- i. The graph is a real function, since it passes the vertical line test. The function is continuous over the interval [-1,1], since it passes the pen-to-paper test over this interval.
- ii. The graph is a real function, since it passes the vertical line test. The function is not continuous over the interval [-1,1], since it doesn't pass the pen-to-paper test over this interval (its value at 0 is undefined).
- (b) (3 points) Calculate the following limits.

i.
$$\lim_{x \to 2} \frac{3x^2 - 6}{x^2 - 3}$$

ii.
$$\lim_{x \to 2} \frac{x^4 - 3x^2 - 4}{x - 2}$$

iii.
$$\lim_{x \to \infty} \frac{x^2 + 4x - 3}{x^3 - 1}$$

Solution:

i. By direct substitution, we have

$$\lim_{x \to 2} \frac{3x^2 - 6}{x^2 - 3} = \frac{3(2)^2 - 6}{(2)^2 - 3} = \frac{12 - 6}{4 - 1} = \boxed{6}$$

ii. If we try to use the substitution formula we get $\frac{0}{0}$, which doesn't make sense. But this tells us that the polynomials $p(x) = x^4 - 3x^2 - 4$ and q(x) = x - 2 both have 2 as a root (that is, p(2) = 0 and q(2) = 0). Therefore $p(x) = (x-2) \cdot p_1(x)$ and of course $q(x) = (x-2) \cdot 1$. We can find $p_1(x)$ by long division:

$$\begin{array}{r}
x^3 + 2x^2 + x + 2 \\
x - 2) \overline{\smash{\big)}\ x^4 - 3x^2 - 4} \\
\underline{-x^4 + 2x^3} \\
2x^3 - 3x^2 \\
\underline{-2x^3 + 4x^2} \\
x^2 \\
\underline{-x^2 + 2x} \\
2x - 4 \\
\underline{-2x + 4} \\
0
\end{array}$$

So we have

$$\lim_{x \to 2} \frac{x^4 - 3x^2 - 4}{x - 2} = \lim_{x \to 2} \frac{\cancel{(x - 2)}(x^3 + 2x^2 + x + 2)}{\cancel{(x - 2)} \cdot 1}$$
$$= 2^3 + 2(2^2) + 2 + 2 = \boxed{20}.$$

1

iii. If we try to use the substitution formula, we get $\frac{\infty}{\infty}$ which is not a real number (doesn't make sense). Whenever x > 0 (which will be the case when $x \to \infty$), we have

$$\frac{x^2 + 4x - 3}{x^3 - 1} = \frac{\frac{x^2 + 4x - 3}{x^3}}{\frac{x^3 - 1}{x^3}}$$
$$= \frac{\frac{1}{x} + \frac{4}{x^2} - \frac{1}{x^3}}{1 - \frac{1}{x^3}}.$$

So we can use the algebra of limits to get

$$\lim_{x \to \infty} \frac{\frac{1}{x} + \frac{4}{x^2} - \frac{1}{x^3}}{1 - \frac{1}{x^3}} = \frac{\lim_{x \to \infty} \frac{1}{x} + \lim_{x \to \infty} \frac{4}{x^2} - \lim_{x \to \infty} \frac{1}{x^3}}{1 - \lim_{x \to \infty} \frac{1}{x^3}}$$
$$= \frac{0 + 0 - 0}{1 - 0} = \boxed{0}.$$

2. (a) (3 points) Calculate the derivatives of the following functions.

i.
$$f(x) = 6x^{1/3} + 2x^{-3/4}$$

ii.
$$f(x) = \ln(x^2 + 3)$$

iii.
$$f(x) = e^{(3x^3 - \ln(x))}$$

Solution:

i. We use the algebra of derivatives to get

$$\frac{d}{dx}\left(6x^{1/3} + 2x^{-3/4}\right) = 6\frac{d}{dx}\left(x^{1/3}\right) + 2\frac{d}{dx}\left(x^{-3/4}\right) = 6 \cdot \frac{1}{3} \cdot x^{-2/3} + 2 \cdot \left(\frac{-3}{4}\right) \cdot x^{-7/4} = 2x^{-2/3} - \frac{3}{2}x^{-7/4}$$

ii. f can be written as the composite function $g \circ h(x) = g(h(x))$, where $h(x) = x^2 + 3$ and $g(x) = \ln(x)$. Therefore, we can apply the chain rule to get

$$f'(x) = g'(h(x)) \cdot h'(x)$$
$$= \frac{1}{h(x)} \cdot 2x$$
$$= \frac{2x}{x^2 + 3}$$

iii. f can be written as the composite function $g \circ h(x) = g(h(x))$, where $g(x) = e^x$ and $h(x) = 3x^3 - \ln(x)$. Therefore, we can apply the chain rule to get

$$f'(x) = g'(h(x)) \cdot h'(x)$$

$$= e^{h(x)} \cdot (6x^2 - \frac{1}{x})$$

$$= (6x^2 - \frac{1}{x}) \cdot e^{(3x^3 - \ln(x))}$$

(b) (2 points) Calculate the Riemann integrals of the following functions.

i.
$$f(x) = 4x^3 + 2x^{-2/3}$$

ii.
$$f(x) = e^{4x} + x^{-3/2}$$

Solution:

i. We use the rules for Riemann integrals to get

$$\left(\int f\right)(x) = \left(\int_0^x 4x^3 \cdot dx\right) + \left(\int_0^x 2x^{-2/3} \cdot dx\right)$$
$$= 4 \cdot \frac{x^4}{4} + 2 \cdot \frac{x^{1/3}}{\frac{1}{3}}$$
$$= \boxed{x^4 + 6x^{1/3}}$$

ii. We use the rules for Riemann integrals to get

$$\left(\int f\right)(x) = \left(\int_0^x e^{4x} \cdot dx\right) + \left(\int_0^x x^{-3/2} \cdot dx\right)$$
$$= \frac{e^{4x} - 1}{4} + \frac{x^{-1/2}}{-\frac{1}{2}}$$
$$= \boxed{\frac{e^{4x} - 1}{4} - 2x^{-1/2}}$$

3. Consider the following function.

$$f(x) = \begin{cases} x^3 - 6(x^2 + 4)^{1/2} & \text{if } x \ge 0\\ 4x^2 - 12 & \text{if } x < 0 \end{cases}$$

- (a) (1 point) Is f continuous at 0?
- (b) (2 points) Is f differentiable at 0?
- (c) (2 points) Does f have a local maximum or a local minimum at 0?

Solution:

(a) When x < 0, $f(x) = 4x^2 + 12$. So we have

$$\lim_{x \to 0^{-}} f(x) = 4(0^{2}) + 12 = 12.$$

When x > 0, $f(x) = x^3 - 6(x^2 + 4)^{1/2}$. So we have

$$\lim_{x \to 0^+} f(x) = 0^3 - 6(0^2 + 4)^{1/2} = 6(4^{1/2}) = 12.$$

Finally, when x = 0, f(x) = 12. Therefore, since $\lim_{x \to 0^-} f(x) = \lim_{x \to 0^+} f(x) = f(0)$, f is continuous at f(x) = 1.

(b) In order to be differentiable at 0, f must be continuous at 0 and the limit $\lim_{h\to 0} D_h f(0)$ must exist. We have just shown that f is continuous at 0, so now we need to show that $\lim_{h\to 0} D_h f(0)$ exists.

We have

$$\lim_{h \to 0^{-}} D_h f(0) = \lim_{h \to 0^{-}} D_h g(0) = g'(0)$$

where $g(x) = 4x^2 - 12$. Since g'(x) = 8x, we have g'(0) = 0

We have

$$\lim_{h \to 0^+} D_h f(0) = \lim_{h \to 0^+} D_h u(0) = u'(0)$$

where $u(x) = x^3 - 6(x^2 + 4)^{1/2}$. Using the chain rule, we have

$$u'(x) = 3x^2 - 3(x^2 + 4)^{-1/2} \cdot 2x$$

and so u'(0) = 0.

Therefore, since $\lim_{h\to 0^-} D_h f(0) = \lim_{h\to 0^+} D_h f(0)$, the derivative of f at 0 exists, and so f is differentiable at 0

4. A company estimates their total cost function to produce x units to be

$$C(x) = 4000 + 0.25x^2$$
 thousand dollars.

The company also estimates that in order to sell x units, each unit must be priced at

$$f(x) = 150 - 0.5x$$
 thousand dollars.

- (a) (2 points) Assuming x units are produced and sold, calculate the total revenue function R(x) and the total profit function P(x).
- (b) (2 points) How many units must be produced and sold to maximize profit? What is the maximum profit?
- (c) (1 point) What price per unit must be charged to maximize profit?

Solution:

(a) The total revenue from selling x units is at f(x) thousand dollars each is

$$R(x) = x \cdot f(x) = 150x - 0.5x^2$$
 thousand dollars.

The total profit from producing and selling x units is

$$P(x) = R(x) - C(x) = 150x - 0.5x^{2} - 4000 - 0.25x^{2} = 150x - 0.75x^{2} - 4000.$$

(b) To maximize profit, we need to find a maximum of the total profit function P. To do so, we first calculate the critical points of P by finding the derivative

$$P'(x) = 150 - 1.5x$$

and then solving P'(x) = 0 to get x = 100 as the only critical point of P. To check if x = 100 is a maximum of P, we need to check that P''(100) < 0. Since P''(x) = -1.5, P''(100) = -1.5, and so x = 100 is a maximum of P.

Therefore, profit will be maximized by producing and selling 100 units. The maximum profit is P(100) = 3500 thousand dollars, or 3.5 million dollars.

- (c) The price per unit that must be charged to maximize profit is f(100) = 100 thousand dollars.
- 5. Like all mammals, humans' bodies are maintained at a fixed temperature (98.6 degrees Fahrenheit) while they are alive. When a person dies, their corpse's temperature decreases as follows: At x hours after death, the corpse's temperature is

$$T(x) = T_0 + (98.6 - T_0)e^{-kx}$$
 degrees Fahrenheit,

where T_0 is the ambient temperature (of the room or environment) and k is a positive constant real number.

Upon arrival, a coroner finds the temperature of a corpse to be 61.6 degrees Fahrenheit. After 1 hour, the coroner measures the corpse's temperature to be 57.2 degrees Fahrenheit. The corpse is in a location whose ambient temperature is 10 degrees Fahrenheit.

- (a) (2 points) If the coroner arrived x hours after the person died, then use the equation $\frac{T(x)}{T(x+1)} = \frac{61.6}{57.2}$ to find the constant k.
- (b) $(1\frac{1}{2} \text{ points})$ If the coroner arrived at 11 PM, when did the person die?
- (c) (1½ points) What was the rate of change of the corpse's temperature (in degrees Fahrenheit per hour) when the coroner arrived?

Solution:

(a) We know that T(x) = 61.6 degrees Fahrenheit and T(x+1) = 57.2 degrees Fahrenheit. Therefore, we have

$$\frac{T(x)}{T(x+1)} = \frac{61.6}{57.2}$$
 i.e.
$$\frac{(98.6 - T_0)e^{-kx}}{(98.6 - T_0)e^{-k(x+1)}} = \frac{61.6}{57.2}$$
 i.e.
$$e^{k(x+1)-kx} = \frac{61.6}{57.2}$$
 i.e.
$$e^k = \frac{61.6}{57.2}$$
 i.e.
$$k = \ln\left(\frac{61.6}{57.2}\right)$$
 i.e.
$$k = \ln 61.6 - \ln 57.2 \approx \boxed{0.074}$$

(b) Since T(x) = 61.6 and $T_0 = 10$ degrees Fahrenheit, we have

$$(98.6 - T_0)e^{-0.074x} = 61.6$$

$$(98.6 - 10)e^{-.074x} = 61.6$$

$$e^{.074x} = \frac{88.6}{61.6}$$

$$.074x = \ln\left(\frac{88.6}{61.6}\right)x = \frac{1}{.074}\ln\left(\frac{88.6}{61.6}\right) \approx 4.91$$

Therefore the coroner arrived about 5 hours after the person died, i.e. the person died at 6 PM.

(c) The rate of change of the corpse's temperature when the coroner arrived was T'(4.91). Since

$$T'(x) = k(T_0 - T(x))$$

we have $T'(4.91) = .074(10 - 61.6) \approx -3.82$ degrees Fahrenheit per hour.
